# Contents

- ⌘ Object of this study
- ⌘ Main failure modes on dike or levee
- ⌘ Limit state equation
- ⌘ Monte Carlo method
- ⌘ Case study---sensitivity analysis  
(1)Overtopping;(2)Piping;(3)Sliding Stability
- ⌘ Some conclusions

# This is a Challenging Topic

- ⌘ According to the existing code of dike design, the designing method of dike is safety margin method based on limit equilibrium analysis, which can't offer reliability index/failure of probability for the practical engineering.
- ⌘ But for the probabilistic design method, the stochastic character of the geometric and strength parameters can be taken into account, so various designing indexes are adopted according to the importance of different components of dike in order to decrease engineering cost.

Conventional → Rational Means

# This is a Challenging Topic

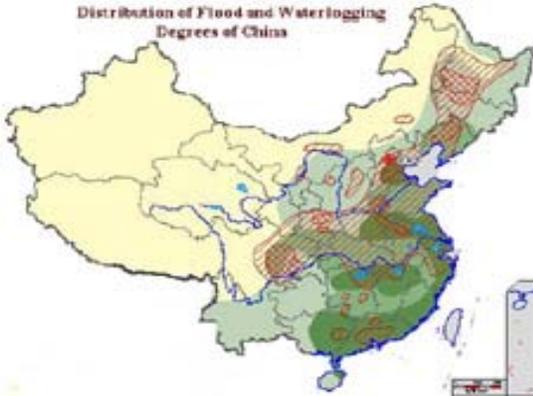

- Recent years, drastic floods have occurred in some large river basins. After flood, dikes must be heightened and widened. Therefore, it is important to study the influence of the variation of Geometry and Geotechnical parameters of flood defense on structural safety or reliability index for design, construction and safety management of dikes.
- In the Netherlands/Australia/USA/Canada, some methods of probabilistic design and safety assessment of embankment and revetment engineering have been discussed by some design guides and handbooks. But in China, further study should be carried out.

The conventional method is valid in China?/!

# How To Combat Floods?

[1998BBC] The decisive battle to beat the flood has begun, and danger may appear at any time, especially around the inland lakes, above the warning level.

Some 3,500 local people are now defending the dikes while soldiers and armed police officers are on standby for rescue work.

# How To Combat Floods?

For Yangtze river alone, some 29 billion yuan (EURO **3.4 billion**) was earmarked during the 1998-2002 period to strengthen 3000 kilometer-long major levees shielding vast area along the river's middle and lower reaches.

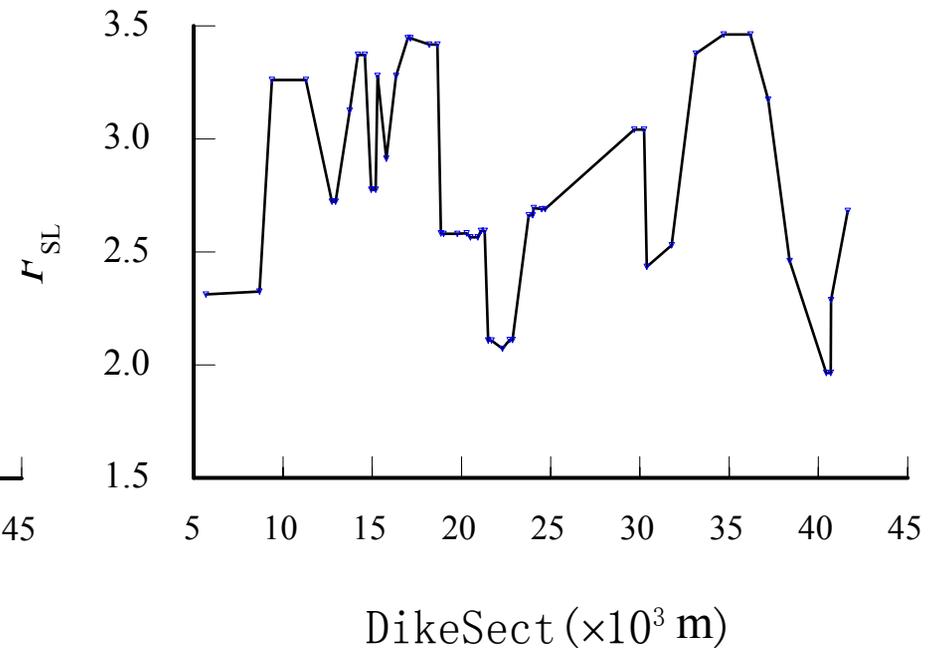

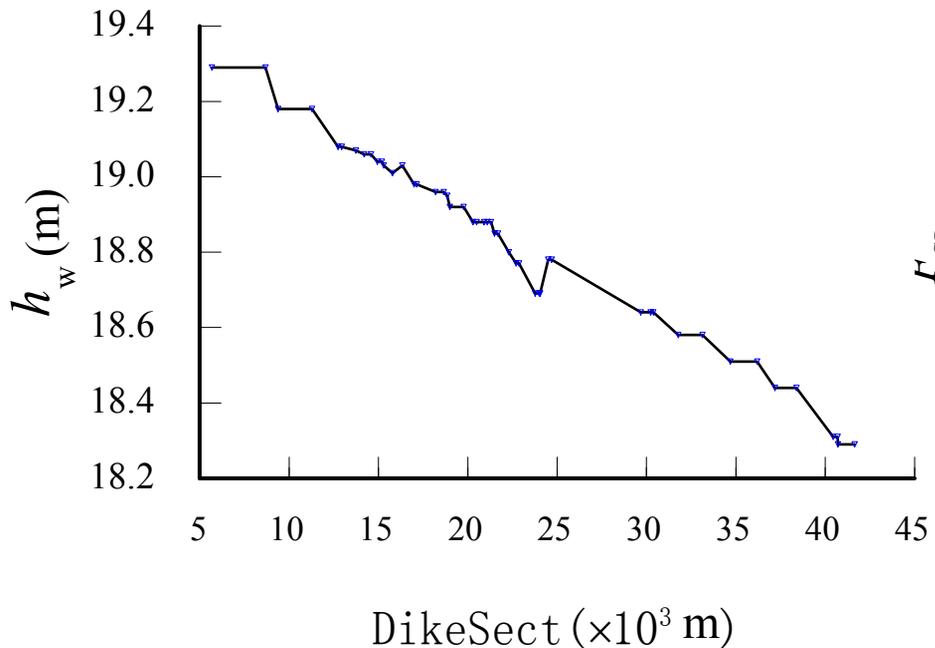

In this case, Wang (Minister of water resources) said confidently that “ in the next **50 to 100** years, there will be no need for China to launch another large-scale reinforcement of the levees”

The process starts with dividing the flood defence system into more detailed subsections

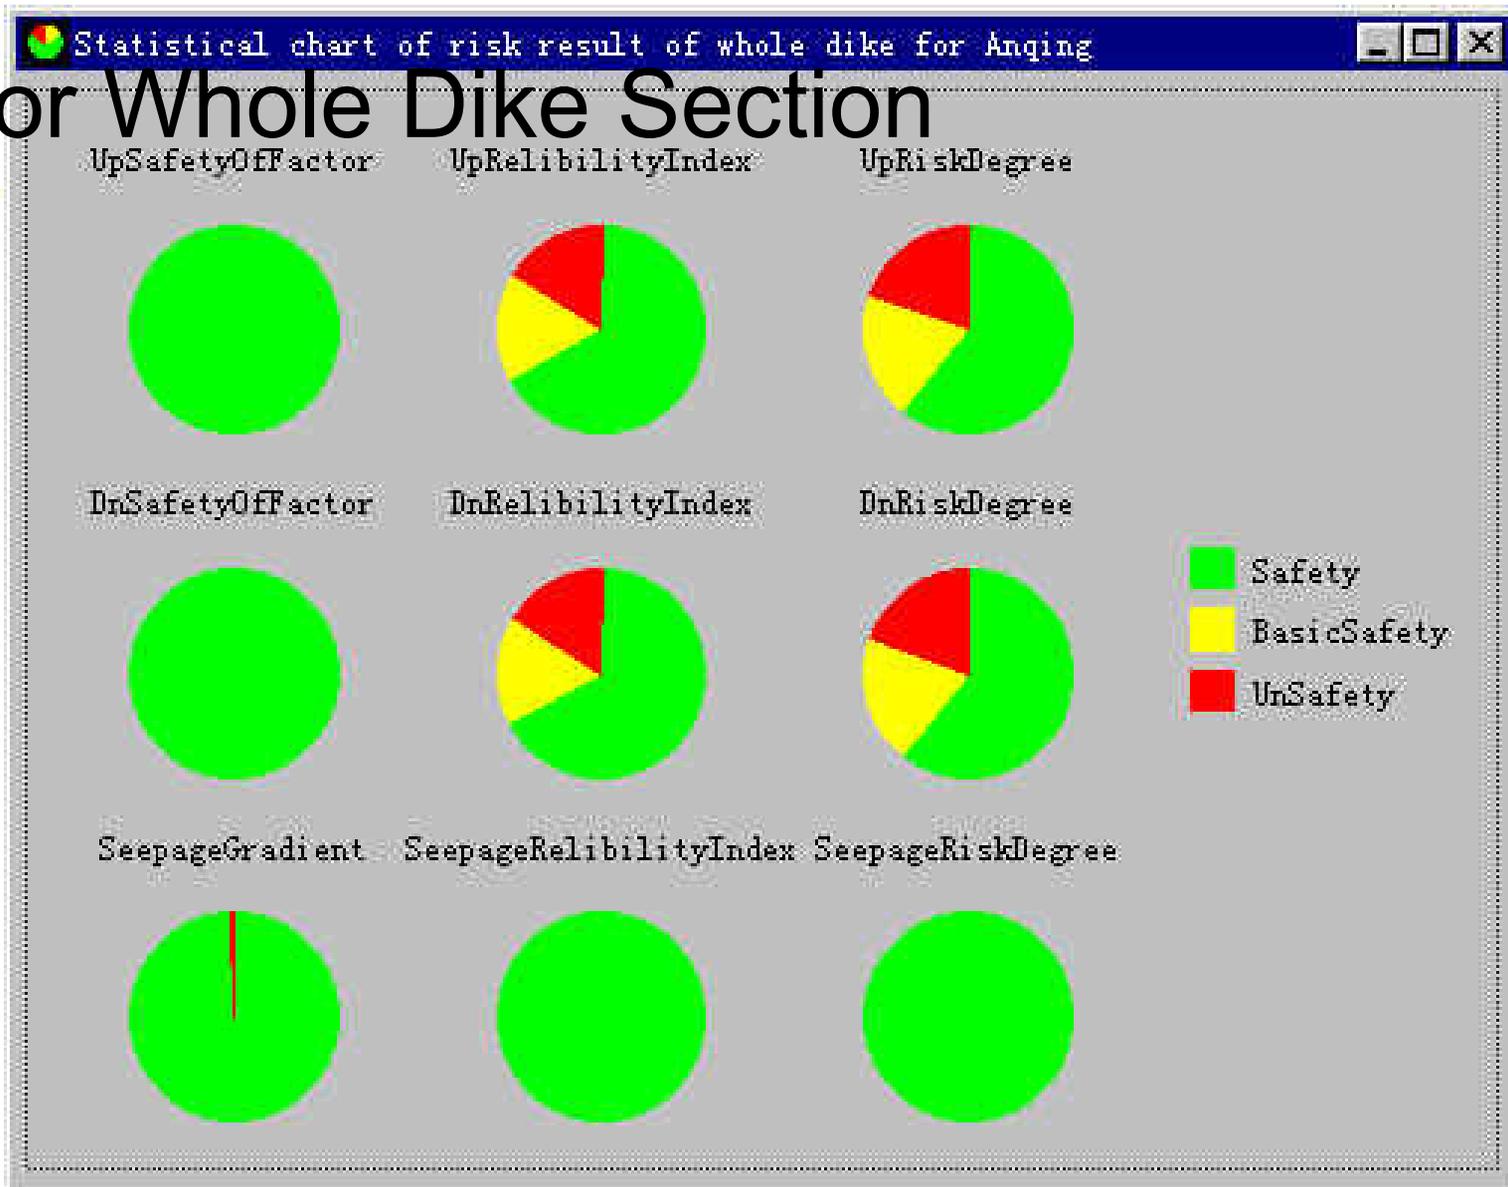

# For Whole Dike Section

**Distribution of Design Water level for whole dike section**

**Distribution of Safety factor of sliding for whole dike section**

# For Whole Dike Section

# Failure Modes

Modes	Dam (China)	Yangtze
Piping	38	54.5
Overtopping	30	
Stability inner slope		15
Stability outer slope	15	
Erosion inner slope		10
Erosion outer slope		
Overflow		

# Limit State Equation

Failure mode	Limit state equation	Icon
Overtopping	$z_1 = h_0 - h_w - h_s - e$	
Piping	$z_2 = \gamma_{nk} d_{ks} - \gamma_w h_{ap} + \gamma_{sb} t_{sb}$	
Sliding	$z_3 = F_{SL} - 1 = M_r / M_o - 1$	

# Calculation Methods

J-C method (FORM)

Monte Carlo method

**Detailed information about these methods**

**can be found in related literatures**

# Monte Carlo Method

## Involves these following steps

- ⌘ (1) Probabilistic distribution models and distribution parameters of the variables related to reliability analysis are determined;
- ⌘ (2) Normally distributed random numbers; The first random sampling of all variables is done, and the result is used in the reliability function;
- ⌘ (3) Repeat random sampling independently for the total number of simulations , and then failure probability is estimated.

# Monte Carlo Method

$$P_f = P(g(x_1, x_2, \dots, x_n) \leq 0)$$

$$I(g(x_1, x_2, \dots, x_n)) = \begin{cases} 1, & g(\cdot) \leq 0 \\ 0, & g(\cdot) > 0 \end{cases}$$

$$\hat{P}_f = \frac{1}{N} \sum I(g(x_1, x_2, \dots, x_n) \leq 0) = \frac{M}{N}$$

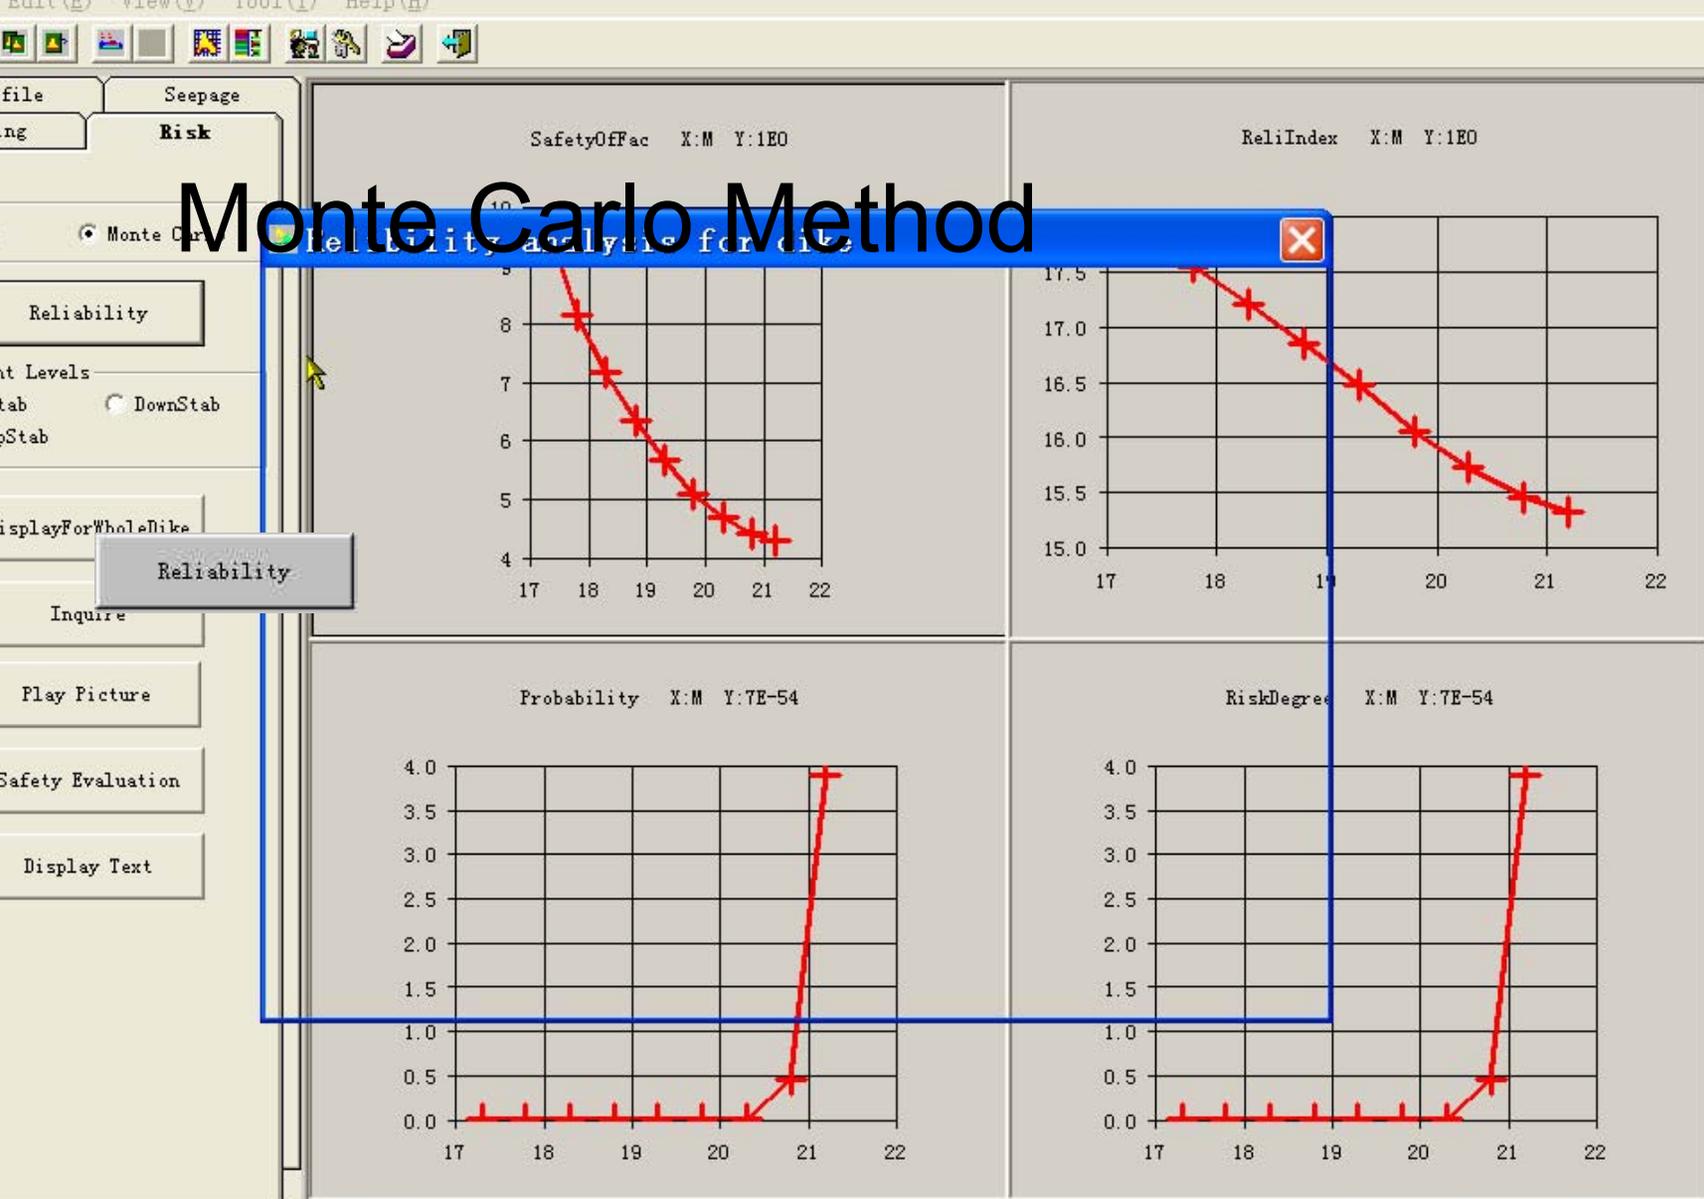

$M$  is the number that  $g(\cdot) \leq 0$

$N$  Is the total number of simulations

# Geometry and Geotechnical Parameters

Variable Description		Unit	Type	Mean value	Standard Deviation
$h_{bc}$	Thickness of clay	m	DV	3.5	
$L_1$	Width of foreland	m	DV	0.0	
$m$	Slope ratio		DV	2.5	
$w$	Crest width	m	DV	5.0	
$t_{sb}$	Thickness of piping-berm	m	DV	0	
$X$	Width of piping-berm	m	DV	0	
$h_0$	Height	m	DV	11.0	
$h_{bs}$	Thickness of sand	m	DV	2.5	
$\gamma_{nk}$	Buoyant unit weight of clay	kN/m <sup>3</sup>	DC	9.0	
$\gamma_w$	Unit weight of water	kN/m <sup>3</sup>	DC	10.0	
$\gamma_{sb}$	Bulk gravity of piping-berm	kN/m <sup>3</sup>	DC	18.0	
$d_{ks}$	Effective thickness of clay	m	RV	3.5	0.7
$h_w$	Flood water level	m	RV	8.3	0.9
$k_c$	Permeability coefficients of clay	m/s	RV	10 <sup>-8</sup>	2*10 <sup>-8</sup>
$k_s$	Permeability coefficients of sand	m/s	RV	10 <sup>-5</sup>	0.75*10 <sup>-5</sup>

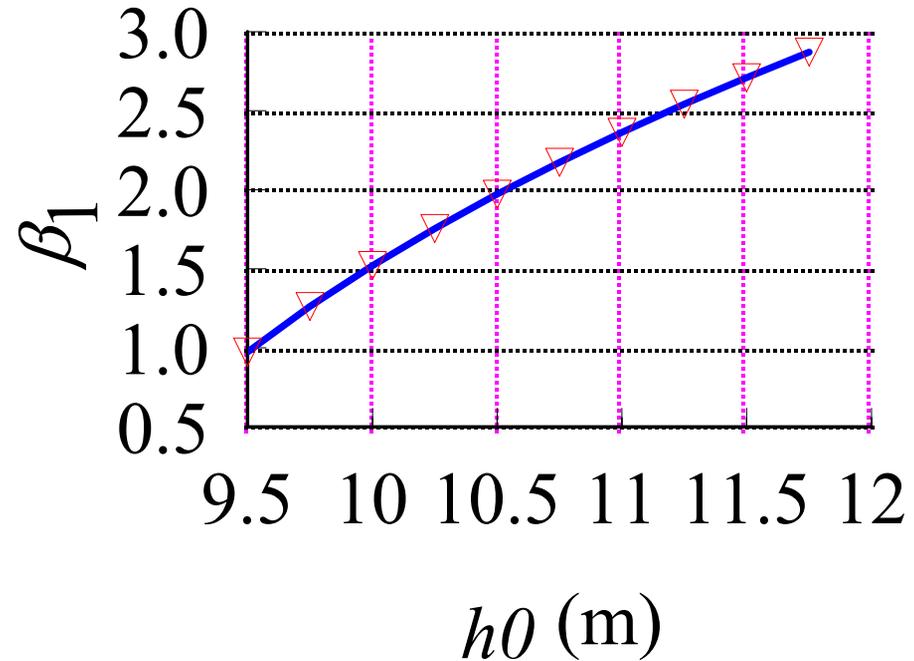

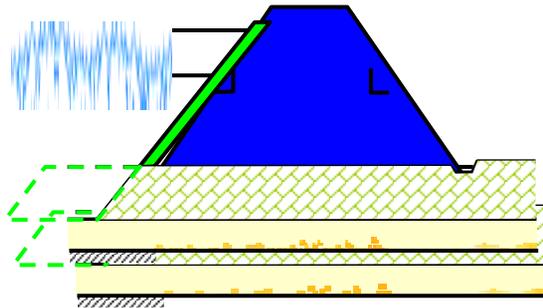

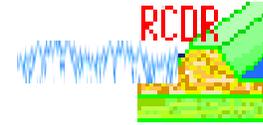

DV--- Design variables; DC--- Deterministic Constants; RV---Random Variables

# Modelling of Overtopping Mechanism

$$z_1 = h_0 - h_w - h_s - e$$

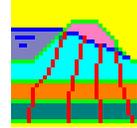

$h_0$	height of dike crest	Normal distribution	11.0m	0.051m
$h_w$	swash height	exponential distribution	8.34m	0.9m
$h_s$	surge height	Normal distribution	0.638	0.44
$e$		Normal distribution		

# Overtopping---ResultA

**Fig. 2 Relation between height of dike and reliability index**

# Modelling of Piping Mechanism

## safety factor

$$F_{\text{CN}} = \Delta H_{\text{strength}} / \Delta H_{\text{loading}} = \frac{\gamma_{\text{nk}} d_{\text{ks}} + \gamma_{\text{sb}} t_{\text{sb}}}{\gamma_{\text{w}} h_{\text{ap}}}$$

residual head of weak permeable stratum

$$h_{\text{ap}} = \frac{h_{\text{w}}}{1 + A * L_{\text{k}} + \tanh A * L_1} e^{-AX}$$

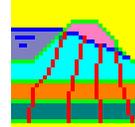

a coefficient

$$A = \sqrt{\frac{k_{\text{c}}}{k_{\text{s}} h_{\text{bc}} h_{\text{bs}}}}$$

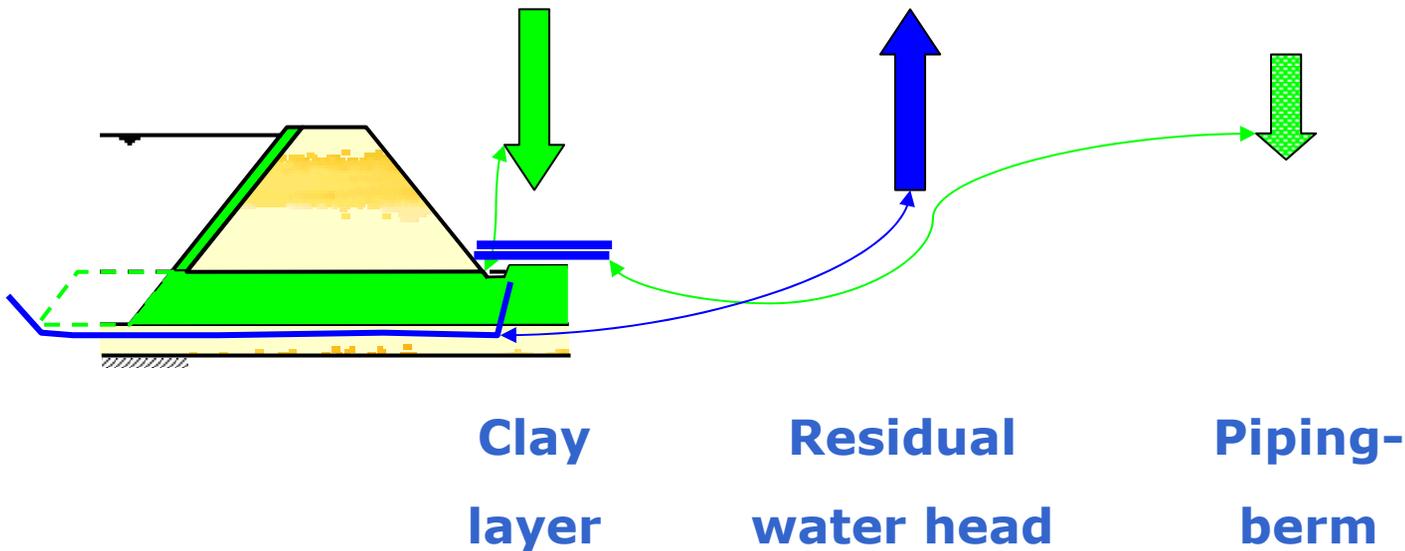

effective seepage path length

$$L_{\text{k}} = 2 * m * h + w + m * h_{\text{bc}}$$

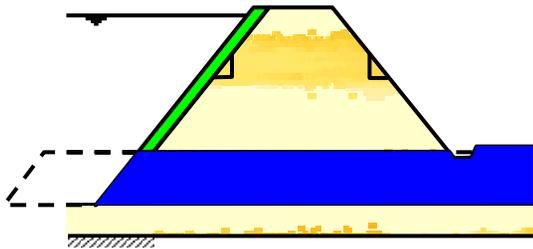

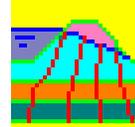

# Modelling of piping mechanism

$$z_2 = \gamma_{nk} d_{ks} - \gamma_w h_{ap} + \gamma_{sb} t_{sb}$$

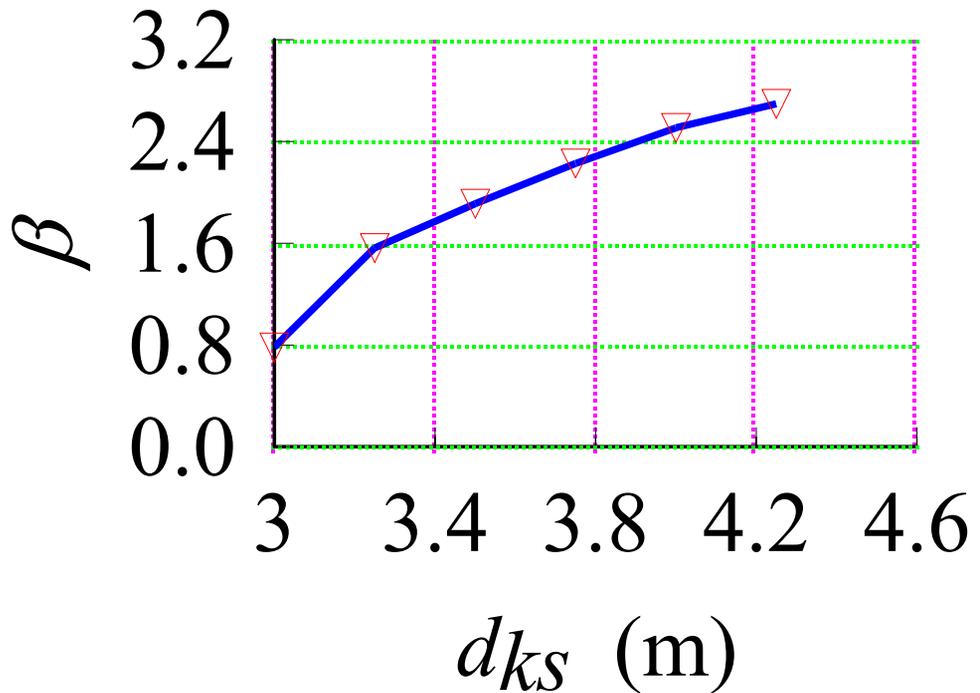

# Piping---ResultB

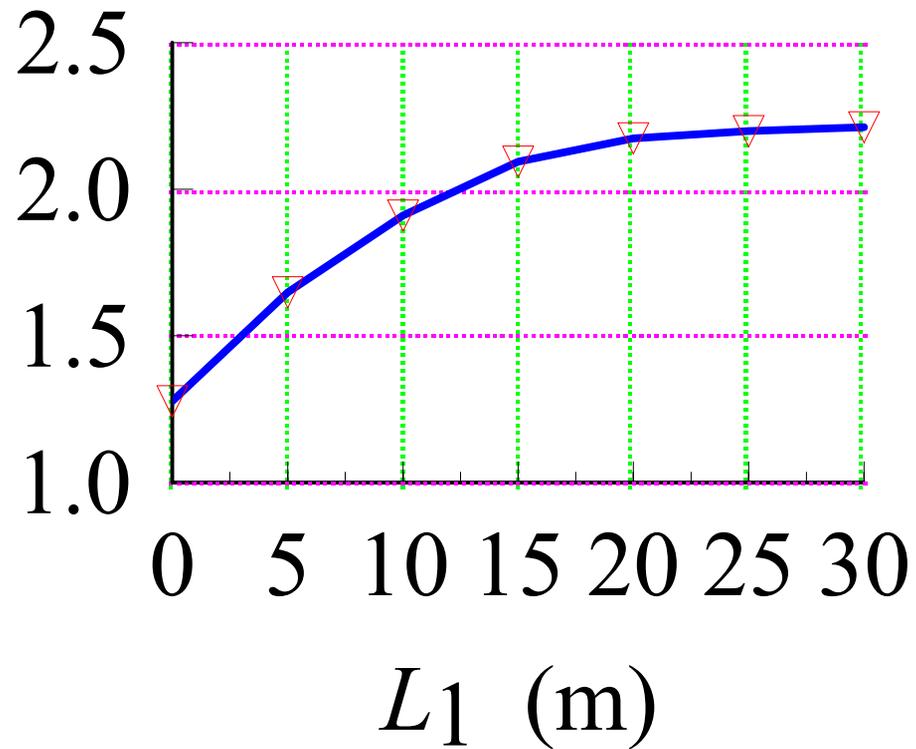

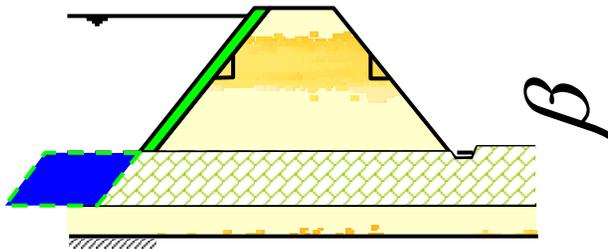

$$F_{CN} = \frac{\gamma_{nk} d_{ks}}{\gamma_w h_{ap}}$$

$$y = kx$$

# Piping---ResultH

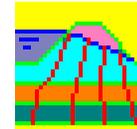

**Fig. 9 Thickness of piping-berm**

# Piping---ResultI

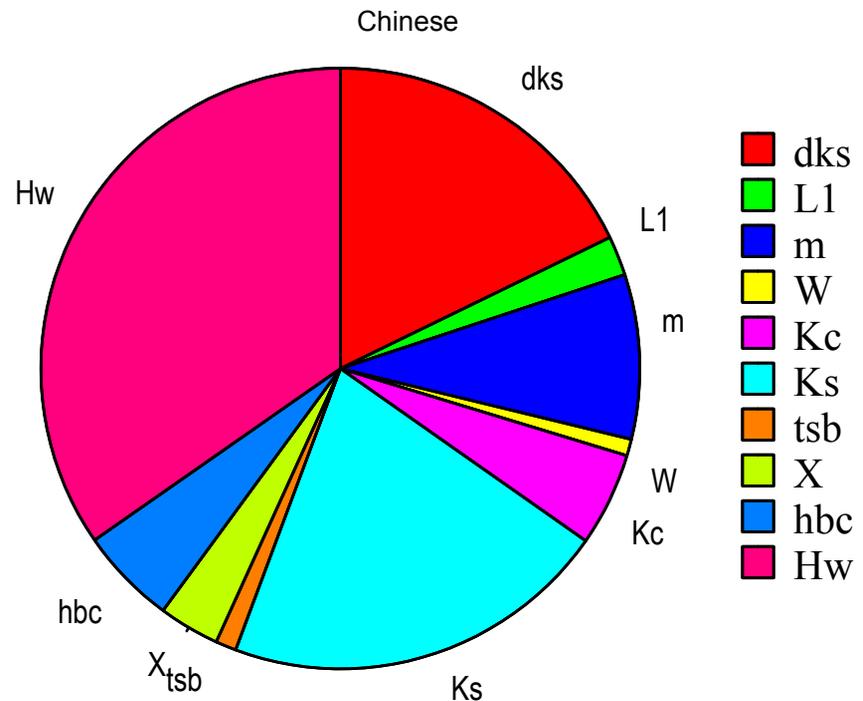

**Fig. 10 Width of piping-berm**

# Piping---ResultJ

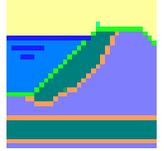

As shown in right Figure, the variables that contribute most to the Reliability index against piping are the water level, thickness of clay layer, seepage coefficient of sand, and the slope ratio.

**Relative influence of the variables on Reliability Index**

# Modelling of Sliding Stability

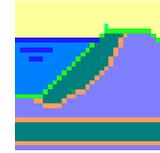

simplified Bishop method

$$F_{SL} = \frac{\sum \frac{1}{m_{\alpha i}} [c'_i b_i + (W_i - u_i b_i) \tan \phi'_i]}{\sum W_i \sin \alpha_i}$$

$$m_{\alpha i} = \cos \alpha_i + \frac{\tan \phi'_i \sin \alpha_i}{F_{SL}}$$

$$z_3 = F_{SL} - 1 = M_r / M_o - 1$$

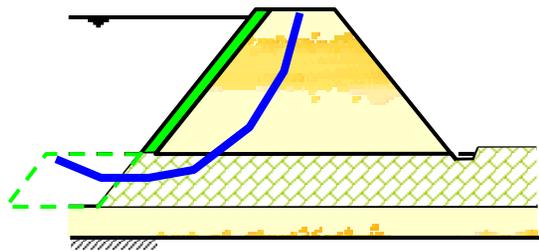

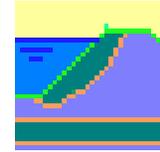

# Slope Stability of Dike

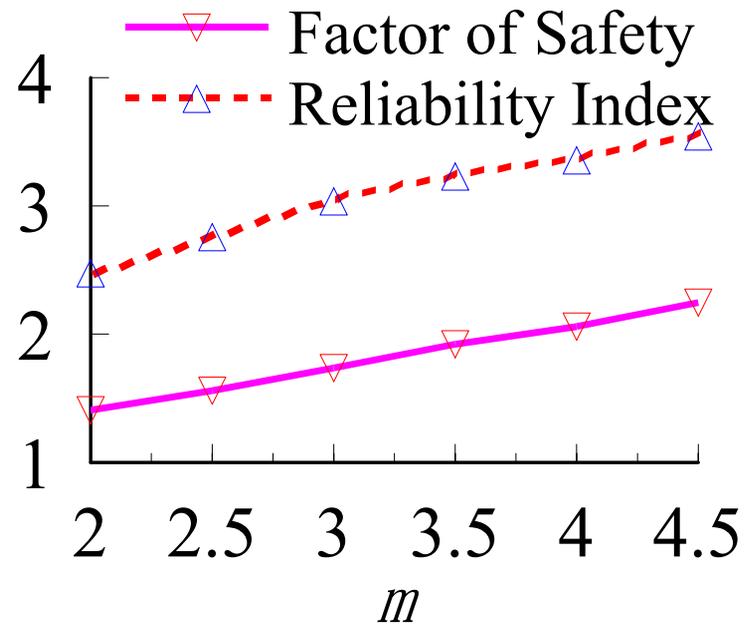

**Table 1** Statistic of geotechnical parameters

Symbol	Name/unit	Distribution type	Mean value	Standard deviation
$c$	Cohensive (kPa)	Normal	12.54	2.8
$\phi$	Inner friction angle( $^{\circ}$ )	Normal	21.58	3.5
$\gamma$	Bulk gravity (kN/m <sup>3</sup> )	Normal	18.84	3.1

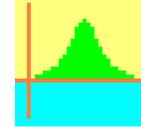

# Sliding---ResultK

$\beta_3$

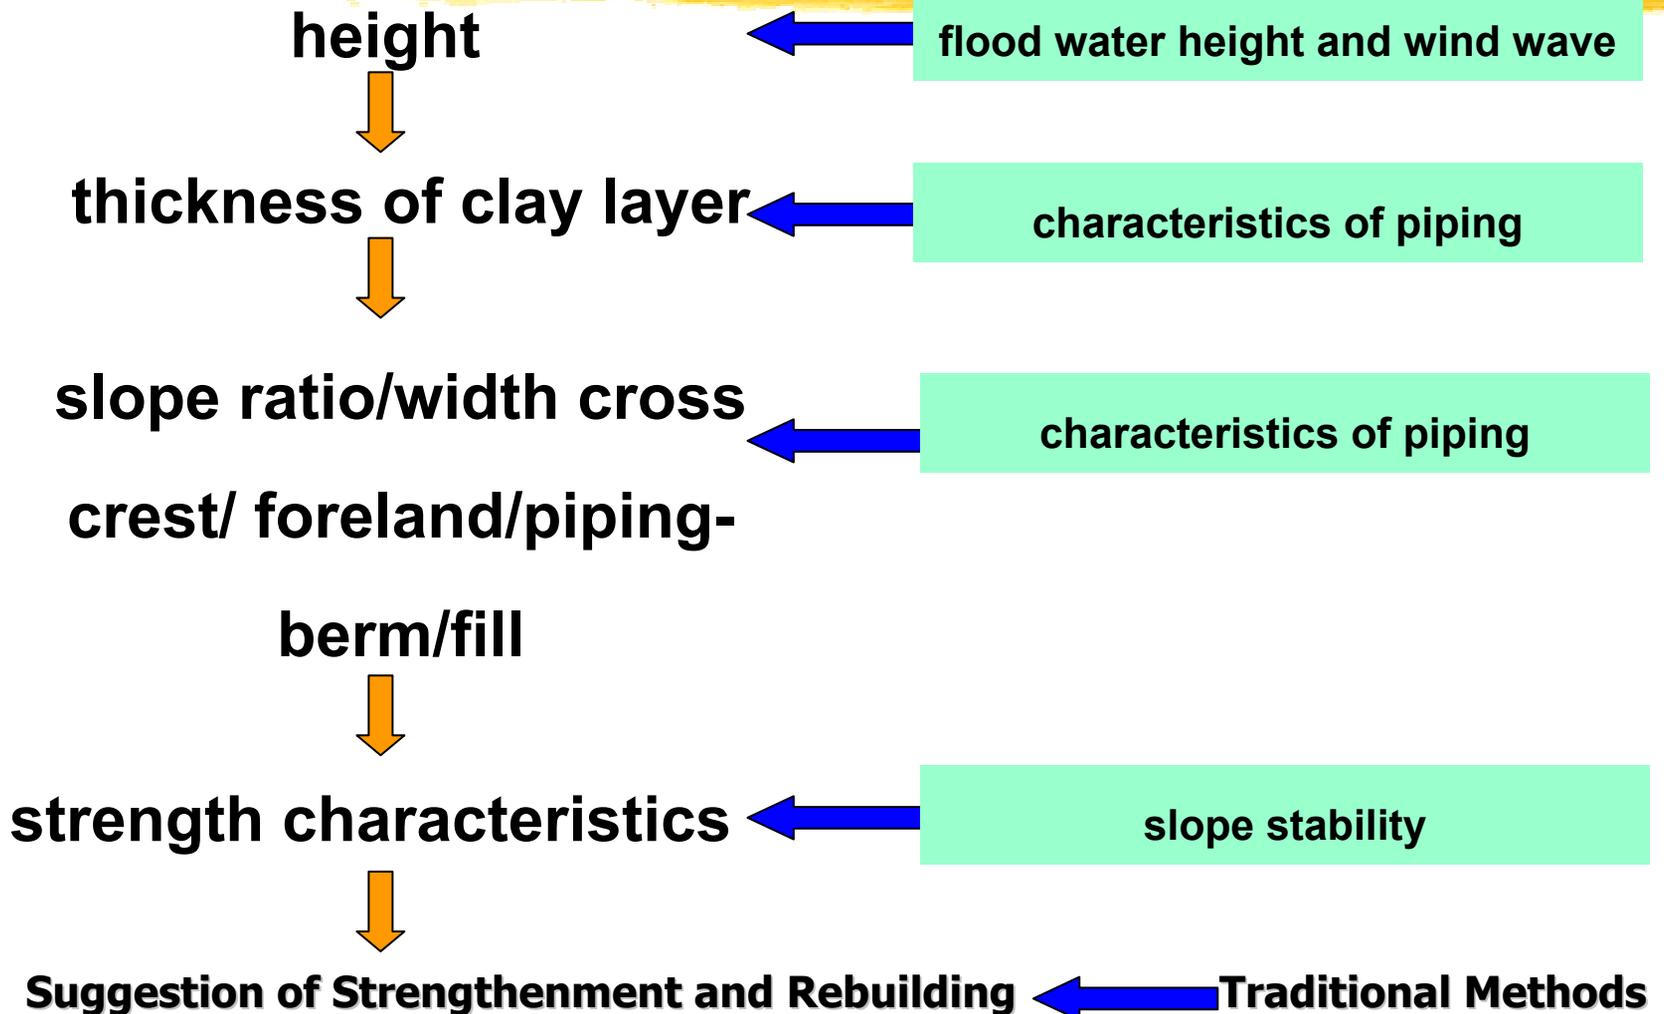

**Fig. 11 Influence of slope ratio**

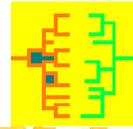

# Probabilistic Design Process

- ❖ **The height ( flood water height and wind wave)**
- ❖ **The thickness of clay layer (characteristics of piping)**
- ❖ **The slope ratio, width cross crest, width of foreland, width of gland, thickness of gland and seepage characteristics of fill (piping).**
- ❖ **Strength characteristics of soil (slope stability analysis).**
- ❖ **The revetment, drainage facility of slope surfaces, impervious facility and drainage facility**

# Diagram of Design Process

# Some Conclusions---(A)

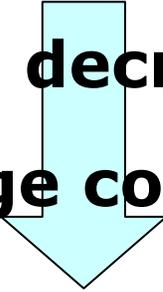

**(1) The reliability index of overtopping increases with the height of dike.**

**(2) The reliability index of seepage stability of dike foundation increases with the slope ratio, width cross crest, width of clay layer of dike foundation, width of foreland, width and thickness of piping-berm behind dike.**

## Some Conclusions---(B)

---

**(3) The reliability index of seepage stability of dike foundation decreases with the increase of seepage coefficient of clay layer and sand layer.**

**(4) The reliability index of slope stability increases with the slope ratio of dike.**

# Areas for Further Study

- ⌘ Cost-benefit analyses in a probabilistic framework should be performed in the future, for the proposed existing dike improvement
- ⌘ Shortcoming ---data collect?/!
- ⌘ Flood duration. Some levees may be subjected to significant water heights for many months. When this occurs, the phreatic surface within the levee will rise, increasing pore pressure and increasing the risk of failure due to under-seepage and slope stability.
